(Dated: December 6, 2006)

In the present work, we quantize a closed Friedmann-Robertson-Walker model in the presence of a positive cosmological constant and radiation. It gives rise to a Wheeler-DeWitt equation for the scale factor which has the form of a Schrödinger equation for a potential with a barrier. We solve it numerically and determine the tunneling probability for the birth of a asymptotically DeSitter, inflationary universe, initially, as a function of the mean energy of the initial wave-function. Then, we verify that the tunneling probability increases with the cosmological constant, for a fixed value of the mean energy of the initial wave-function.

I. INTRODUCTION

Since the pioneering work in quantum cosmology due to DeWitt [1], many physicists have worked in this theory. The main motivation behind quantum cosmology is a consistent explanation for the origin of our Universe. So far, the most appealing explanation is the spontaneous *creation from nothing* [2, 3, 4, 5, 6, 7]. In that picture for the origin of the Universe, the Universe is a quantum mechanical system with zero size. There is a potential barrier that the Universe may tunnel with a well-defined, non-zero probability. If the Universe actually tunnels, it emerges to the right of the barrier with a definite size. The application of the *creation from nothing* idea in minisuperspace models has led to several important results. The wave-function of the Universe satisfies the Wheeler-DeWitt equation [1, 8]. Therefore, one needs to specify boundary conditions in order to solve that equation and find a unique and well-defined wave function. The motivation to obtain a wave-function that represents the *creation from nothing* has led to the introduction of at least three proposals for the boundary conditions for the wave-function of the Universe [7]. The inflationary period of the Universe appears very naturally from the *creation from nothing* idea. That is the case because most of the minisuperspace models considered so far have a potential that decreases, without a limit, to the right of the barrier. It gives rise to a period of unbounded expansion which is interpreted as the inflationary period of the Universe [7]. Also, it was shown by several authors that an open inflationary universe may be created from nothing, in theories of a single scalar field for generic potentials [9, 10, 11]. Another important issue is the particle content in the Universe originated during the *creation from nothing* process [6, 12, 13].

In the present work, we would like to compute the tunneling probability (TP) for a closed Friedmann-Robertson-Walker (FRW) model in the presence of a positive cosmological constant and radiation. The radiation is treated by means of the variational formalism developed by Schutz [14]. That model has already been treated quantum mechanically using the ADM formalism and the Dirac quantization for constrained systems [7, 15, 16]. The wave-function, for that model, was calculated in the WKB approximation. Here, we compute the wave-function and TP exactly, without any approximation. It will be done by means of a numerical calculation. As we shall see, this model has two free parameters: the radiation energy and the cosmological constant. Therefore, we will obtain the TP as a function of those two parameters. The main motivation of that result, is trying to contribute to a long standing debate about which is the most appropriate set of initial conditions for the wave-function of the Universe. The most well-known proposals for the set of initial conditions are the *tunneling* one, due to A. Vilenkin [3], and the *no-boundary*

one, due to J. B. Hartle and S. W. Hawking [4]. The application of those proposals for simple models showed that they give some different predictions for the initial evolution of the Universe [3, 4, 13, 15, 16, 17, 18]. One of such predictions, which we shall explore here, is the initial energy of the Universe right after its nucleation. The *tunneling* wave function predicts that the Universe must nucleate with the largest possible vacuum energy whereas the *no-boundary* wave function predicts just the opposite [7]. In terms of our results, if one assumes that the cosmological constant describes a vacuum energy, it is important to see if TP increases or decreases with the cosmological constant, for fixed radiation energy. The first behavior favors the *tunneling* wave function and the latter favors the *no-boundary* wave function.

In the next Section, we describe the classical dynamics of the present cosmological model. We write the super-hamiltonian constraint and the Hamilton's equations. We solve the Hamilton's equations and find the general solution of the model. Then, we qualitatively describe all possible classical evolutions. In Section III, we canonically quantize the model and obtain the corresponding Wheeler-DeWitt equation. We solve it, numerically, for particular values of the radiation energy and the cosmological constant. We show the square modulus of the wave-function of the universe as a function of the scalar factor. The tunneling process can be readily seen from that figure. The Section IV is divided in three subsections with the main results of the paper. In the first subsection IV A, we start introducing the tunneling probability, then we evaluate its dependence on the radiation energy. We obtain that, the TP increases with the radiation energy for a fixed cosmological constant. In the following subsection IV B, we give a detailed comparison between the exact TP, computed in the previous subsection, and the corresponding WKB tunneling probability. In the final subsection IV C of this section, we evaluate the dependence of the exact TP with the cosmological constant. We obtain that, the TP increases with the cosmological constant for a fixed radiation energy. Finally, in Section V we summarize the main points and results of our paper.

II. THE CLASSICAL MODEL

The Friedmann-Robertson-Walker cosmological models are characterized by the scale factor $a(t)$ and have the following line element,

$$ds^2 = -N^2(t)dt^2 + a^2(t) \left(\frac{dr^2}{1 - kr^2} + r^2 d\Omega^2 \right), \quad (1)$$

where $d\Omega^2$ is the line element of the two-dimensional sphere with unitary radius, $N(t)$ is the lapse function and k gives the type of constant curvature of the spatial sections. Here, we are considering the case with positive curvature $k = 1$ and we are using the natural unit system, where $\hbar = c = G = 1$. The matter content of the model is represented by a perfect fluid with four-velocity $U^\mu = \delta_0^\mu$ in the comoving coordinate system used, plus a positive cosmological constant. The total energy-momentum tensor is given by,

$$T_{\mu,\nu} = (\rho + p)U_\mu U_\nu - pg_{\mu,\nu} - \Lambda g_{\mu,\nu}, \quad (2)$$

where ρ and p are the energy density and pressure of the fluid, respectively. Here, we assume that $p = \rho/3$, which is the equation of state for radiation. This choice may be considered as a first approximation to treat the matter content of the early Universe and it was made as a matter of simplicity. It is clear that a more complete treatment should describe the radiation, present in the primordial Universe, in terms of the electromagnetic field.

Einstein's equations for the metric (1) and the energy momentum tensor (2) are equivalent to the Hamilton equations generated by the super-hamiltonian constraint

$$\mathcal{H} = -\frac{p_a^2}{12a} - 3a + \Lambda a^3 + \frac{p_T}{a}, \quad (3)$$

where p_a and p_T are the momenta canonically conjugated to a and T the latter being the canonical variable associated to the fluid [19]. The total Hamiltonian is given by $N\mathcal{H}$ and we shall work in the conformal gauge, where $N = a$.

The classical dynamics is governed by the Hamilton equations, derived from the total Hamiltonian $N\mathcal{H}$, namely

$$\left\{ \begin{array}{l} \dot{a} = \frac{\partial(N\mathcal{H})}{\partial p_a} = -\frac{p_a}{6}, \\ \dot{p}_a = -\frac{\partial(N\mathcal{H})}{\partial a} = 6a - 4\Lambda a^3, \\ \dot{T} = \frac{\partial(N\mathcal{H})}{\partial p_T} = 1, \\ \dot{p}_T = -\frac{\partial(N\mathcal{H})}{\partial T} = 0. \end{array} \right. \quad (4)$$

Where the dot means derivative with respect to the conformal time $\tau \equiv Nt$. We also have the constraint equation $\mathcal{H} = 0$. We have the following solutions for the system (4):

$$T(\tau) = \tau + c_1, a(\tau) = \frac{\sqrt{6\beta}}{\sqrt{3 + \sqrt{9 - 12\Lambda\beta}}} \operatorname{sn} \left(\frac{\sqrt{18 + 6\sqrt{9 - 12\Lambda\beta}}(\tau - \tau_0)}{6}, \sigma \right), \quad (5)$$

where c_1 , β and τ_0 are integration constants, sn is the Jacobi's elliptic sine [20] of modulus σ given by

$$\sigma = \frac{\sqrt{2}}{2} \sqrt{\frac{-2\beta\Lambda + 3 - \sqrt{9 - 12\Lambda\beta}}{\Lambda\beta}}. \quad (6)$$

In the case studied here $\Lambda > 0$, the radiation energy β can take values in the domain, $\beta \leq 3/(4\Lambda)$. If one substitutes values of β such that $\beta < 3/(4\Lambda)$ in Eqs. (5) and (6), the scale factor, starting from zero, expands to a maximum size and then recollapse. On the other hand, if $\beta = 3/(4\Lambda)$, the scalar factor initially decelerates and then, enter the regime of unbounded expansion.

III. THE QUANTUM MODEL

We wish to quantize the model following the Dirac formalism for quantizing constrained systems [21]. First we introduce a wave-function which is a function of the canonical variables \hat{a} and \hat{T} ,

$$\Psi = \Psi(\hat{a}, \hat{T}). \quad (7)$$

Then, we impose the appropriate commutators between the operators \hat{a} and \hat{T} and their conjugate momenta \hat{P}_a and \hat{P}_T . Working in the Schrödinger picture, the operators \hat{a} and \hat{T} are simply multiplication operators, while their conjugate momenta are represented by the differential operators

$$p_a \rightarrow -i \frac{\partial}{\partial a}, \quad p_T \rightarrow -i \frac{\partial}{\partial T}. \quad (8)$$

Finally, we demand that the operator corresponding to $N\mathcal{H}$ annihilate the wave-function Ψ , which leads to Wheeler-DeWitt equation

$$\left(\frac{1}{12} \frac{\partial^2}{\partial a^2} - 3a^2 + \Lambda a^4 \right) \Psi(a, \tau) = -i \frac{\partial}{\partial \tau} \Psi(a, \tau), \quad (9)$$

where the new variable $\tau = -T$ has been introduced.

The operator $N\hat{\mathcal{H}}$ is self-adjoint [22] with respect to the internal product,

$$(\Psi, \Phi) = \int_0^\infty da \, \Psi(a, \tau)^* \Phi(a, \tau), \quad (10)$$

if the wave functions are restricted to the set of those satisfying either $\Psi(0, \tau) = 0$ or $\Psi'(0, \tau) = 0$, where the prime $'$ means the partial derivative with respect to a . Here, we consider wave functions satisfying the former type of boundary condition and we also demand that they vanish when a goes to ∞ .

The Wheeler-DeWitt equation (9) is a Schrödinger equation for a potential with a barrier. We solve it numerically using a finite difference procedure based on the Crank-Nicolson method [23], [24] and implemented in the program GNU-OCTAVE. In fact, numerically one can only treat the *tunneling from something* process, where one gives a initial wave function with a given mean energy, very concentrated in a region next to $a = 0$. That initial condition fixes an energy for the radiation and the initial region where a may take values. Our choice for the initial wave function is the following normalized gaussian,

$$\Psi(a, 0) = \left(\frac{8192E^3}{\pi} \right)^{1/4} a e^{(-4Ea^2)}, \quad (11)$$

where E is the radiation energy. $\Psi(a, 0)$ is normalized by demanding that the integral of $|\Psi(a, 0)|^2$ from 0 to ∞ be equal to one and its mean energy be E . After one gives the initial wave function, one leaves it evolve following the appropriate Schrödinger equation until it reaches infinity in the a direction. Numerically, one has to fix the infinity at a finite value. In the present case we fix $a_{max} = 30$ as the infinity in the a direction. The general behavior of the solutions, when E is smaller than the maximum value of the potential barrier, is an everywhere well-defined, finite, normalized wave packet. Even in the limit when the scale factor goes to zero. For small values of a the wave packet have great amplitudes and oscillates rapidly due to the interaction between the incident and reflected components. The transmitted component is an oscillatory wave packet that moves to the right and has a decreasing amplitude which goes to zero in the limit when a goes to infinity. As an example, we solve eq. (9) with $\Lambda = 0.0121$. For this choice of Λ the potential barrier has its maximum value equal to 185.95. In order to see the tunneling process, we choose $E = 185$ for the initial wave function eq. (11). For that energy, we compute the points where it meets the potential barrier, the left (a_{ltp}) and right (a_{rtp}) turning points. They are, $a_{ltp} = 10.7287$ and $a_{rtp} = 11.5252$. In figure 1, we show $|\Psi(a, t_{max})|^2$ for the values of Λ and E , given above, at the moment (t_{max}) when Ψ reaches infinity. For more data on this particular case see table II, in

the appendix. It is important to mention that the choice of the numerical values for Λ and E above and in the following examples, in the next section, were made simply for a better visualization of the different properties of the system.

FIG. 1: $|\Psi(a, t_{max})|^2 \equiv \rho$, for $\Lambda = 0.0121$, $E = 185$ at the moment t_{max} when Ψ reaches infinity, located at $a = 30$.

IV. TUNNELING PROBABILITIES

A. Tunneling probability as a function of E

We compute the tunneling probability as the probability to find the scale factor of the universe to the right of the potential barrier. In the present situation, this definition is given by the following expression,

$$TP_{int} = \frac{\int_{a_{rtp}}^{\infty} |\Psi(a, t_{max})|^2 da}{\int_0^{\infty} |\Psi(a, t_{max})|^2 da}, \quad (12)$$

where, as we have mentioned above, numerically ∞ has to be fixed to a maximum value of a . Here, we are working with $a_{max} = 30$.

Since, by normalization, the denominator of Eq. (12) is equal to the identity, TP_{int} is effectively given by the numerator of Eq. (12). We consider initially the dependence of TP on the energy E . Therefore, we compute TP_{int} for 47 values of the radiation energy for a fixed $\Lambda = 0.01$. For this choice of Λ the potential barrier has its maximum value equal to 225. In order to study the tunneling process, we fix the mean energies of the various $\Psi(a, 0)$'s eq. (11) to be smaller than that value. In table I, in the appendix, we can see, among other quantities, the different values of

the energy E , TP_{int} , a_{ltp} and a_{rtp} for each energy. In figure 2, we see the tunneling probability as functions of E . Due to the small values of some TP 's, we plot the logarithms of the TP 's against E .

FIG. 2: $\log TP_{int}$ for different radiation energies (E) for a fixed $\Lambda = 0.01$.

We may draw an important conclusion from figure 2. The tunneling probability grows with E for a fixed Λ . It means that, it is more likely for the universe, described by the present model, to nucleate with the highest possible radiation energy.

B. Exact tunneling probability versus WKB tunneling probability

Let us, now, compare the exact tunneling probability represented by TP_{int} eq. (12) with the approximated WKB tunneling probability (TP_{WKB}). The TP_{WKB} is defined by the ratio between the square modulus of the transmitted amplitude of the WKB wave-function and the square modulus of the incident amplitude of the WKB wave-function [25], [26]. For the present situation, it is given by the following expression [26],

$$TP_{WKB} = \frac{4}{\left(2\theta + \frac{1}{(2\theta)}\right)^2}, \quad (13)$$

where,

$$\theta = \exp \left(\int_{a_{ltp}}^{a_{rtp}} da \sqrt{12(3a^2 - \Lambda a^4 - E)} \right). \quad (14)$$

In table I, in the appendix, we have an entry for TP_{WKB} . It means that, we computed the values of the TP_{WKB} s for each energy used to compute the TP_{int} s, in the case where $\Lambda = 0.01$. In figure 3, we see a comparison between both tunneling probabilities as functions of E . Due to the small values of some TP 's, we plot the logarithms of the TP 's against E .

FIG. 3: Comparison between $\log TP_{WKB}$ (circles) and $\log TP_{int}$ (heavy line) for different radiation energies (E) for a fixed $\Lambda = 0.01$.

As we can see from figure 3, the tunneling probabilities disagree for most values of E . They only agree for values of E very close to the top of the potential barrier. The disagreement between the two TP 's for most values of E is not difficult to understand. Due to the definition of the WKB wave function, it must be a good approximation to the exact wave function in regions where the potential does not vary very much [25], [26]. In the present case the potential does not vary very much only close to the top of the barrier. Therefore, in that region one expects that the WKB predictions are in agreement with the predictions coming from the exact solution of the problem.

As we have mentioned above, numerically one can only treat the *tunneling from something* process, where one gives a initial wave function with a given mean energy, very concentrated in a region next to $a = 0$. Then, if we take $E = 0$ the TP_{int} will be zero. On the other hand, we may

have an idea how TP_{int} behaves near $E = 0$ from figure 2. From table I, in the appendix, one can see that $TP_{WKB} = 7.0246 \times 10^{-522}$ when $E = 0$.

Finally, we may compute the time (τ) the universe would take, for each energy, to nucleate. In order to understand the meaning of τ , consider a photon that composes the radiation which is initially confined to the left of the potential barrier. Then, compute the emission probability of that photon, per unit of time. We may invert it to obtain τ , the time the photon would take to escape the potential barrier. If we consider τ as the time it takes for the most part of the photons to escape the barrier, we obtain the time the universe would take, for each energy, to appear at the right of the barrier. In the present situation, τ is given by the following expression [25],

$$\tau = 2a_{ltp} \frac{1}{PT_{int}} \quad (15)$$

From table I, in the appendix, we may see the values of τ , for each energy. It is clear by the results that, the smaller the energy E the longer it will take for the universe to nucleate.

C. Tunneling probability as a function of Λ

We would like to study, now, how the tunneling probability depends on the cosmological constant. In order to do that, we must fix an initial energy E for the radiation and compute the TP_{int} for various values of Λ . We choose $E = 185$ and 22 different values of Λ , such that, the maximum energy of the potential barrier (PE_{max}), for each Λ , is greater than 185. The values of Λ , TP_{int} , PE_{max} , τ , a_{ltp} and a_{rtp} are given in table II, in the appendix. With those values, we construct the curve TP_{int} versus Λ , shown in figure 4. Due to the small values of some TP 's, we plot the logarithms of the TP 's against Λ . From figure 4, it is clear that the tunneling probability increases with Λ for a fixed E . Therefore, it is more likely for the universe, described by the present model, to nucleate with the highest possible cosmological constant. If we assume that Λ describes a vacuum energy, this result is qualitatively in accordance with the prediction of the *tunneling* wave function due to A. Vilenkin [3].

V. CONCLUSIONS.

In the present work, we canonically quantized a closed Friedmann-Robertson-Walker (FRW) model in the presence of a positive cosmological constant and radiation. The radiation was treated by means of the variational formalism developed by Schutz [14]. The appropriate Wheeler-DeWitt

FIG. 4: $\log TP_{int}$ for 22 different values of Λ for a fixed $E = 185$.

equation for the scale factor has the form of a Schrödinger equation for a potential with a barrier. We solved it, numerically, and determined the tunneling probability for the birth of an asymptotically DeSitter, inflationary universe, as a function of the radiation energy and the cosmological constant. Then, we verified that the tunneling probability increases with the radiation energy, for a fixed cosmological constant. We also gave a detailed comparison between the exact TP, computed here, and the corresponding WKB tunneling probability. Finally, we evaluated the dependence of the exact TP with the cosmological constant. We obtained that, the TP increases with the cosmological constant for a fixed radiation energy. If one assumes that the cosmological constant describes a vacuum energy, the latter result seems to be in accordance with the predictions of the *tunneling* wave function [7].
